

Dev-Laptop Side, Shipped

Commit `28cb649` pushed to `kat-e8/manpage`, plain fast-forward. Everything the dev laptop owns in this plan is now done.

commit: 28cb649 2026-08-16

01 What shipped

GIT COMMIT -M ...

Add immutable-image CI/CD pipeline (build/deploy workflows)

- `docker-compose.yml`: image: alongside build: for all five buildable services, tagged by `IMAGE_TAG` (defaults to `:dev` locally)
- `docker-compose.deploy.yml`: new, image-only, no build: keys -- the file that actually runs on clubuntu
- `.github/workflows/build.yml`: builds and pushes on every push to main
- `.github/workflows/deploy.yml`: pulls and runs on a git tag, writing into the persistent `/opt/docker/manpage` deploy directory on clubuntu

7 files changed, 144 insertions(+)

`git push origin main` → `4b0d0fc..28cb649 main → main`. No force needed this time — a plain fast-forward, exactly what a healthy push looks like.

02 Dev-laptop checklist, closed out

#	TASK	STATUS
1	Create GitHub repo	Done
2	<code>git init</code> , commit, remote, push	Done
3	<code>image:</code> added to <code>docker-compose.yml</code>	Done
4	<code>docker-compose.deploy.yml</code> created	Done
5	Both workflow files created	Done

#	TASK	STATUS
6	Committed and pushed	Done

03 What's waiting on clubuntu

a push to main right now would queue a build job –
it just has nothing self-hosted to claim it yet

This is expected, not broken. GitHub happily queues jobs with no matching runner; they just sit there until one registers.

04 Next

- ▶ Separate session on clubuntu: confirm `/opt/docker/manpage` has a working `.env`
- ▶ Create the dedicated, `docker`-group-only user for the runner
- ▶ Register and start the self-hosted runner as a systemd service
- ▶ Then: a real push to `main` is the first live test of `build.yml`
