

The First Live Deploy

Tag `v0.1.0`, pushed once — and for the first time, something actually changed on clubuntu without anyone typing a command there.

```
tag: v0.1.0 → commit 9992ba4 2026-08-16
```

00 What this actually tests

Doc 9 proved *build* — code in, images in the registry. It never touched a running container. This is the other half: a tag resolving to a commit, that commit's already-built images getting pulled (not rebuilt), and the stack actually coming up on clubuntu. The whole reason every push builds and only a tag deploys, from the very first planning doc, was to make this moment cheap and safe rather than something to be nervous about.

01 What happened, in order

Every step here matches doc 4's plan exactly — this is that diagram, confirmed as real behavior rather than intent.

02 Verified

CONTAINER	IMAGE	STATUS
generic-mcp-gateway	gateway:9992ba4	Up, healthy

CONTAINER	IMAGE	STATUS
coder-commands-mcp	coder-commands-mcp:9992ba4	Up
codercommands-docker-mcp	docker-mcp:9992ba4	Up
codercommands-postgres	postgres:17	Up, healthy
codercommands-postgres-mcp	postgres-mcp:9992ba4	Up, healthy
codercommands-sync	sync:9992ba4	Up

```
$ curl http://localhost:8100/healthz
{"status":"ok"}
```

Every service resolved to exactly the tag the deploy step set — none defaulted, none mismatched. The gateway, the one published port, answers for real.

03 The whole loop, closed

Same diagram as the very first plan (Deployment series, doc 6) — every box now backed by a real, verified run instead of intent.

Not yet exercised: a rollback tag. The mechanism is identical to this one — an older SHA instead of the newest — but hasn't actually been run once for real.
